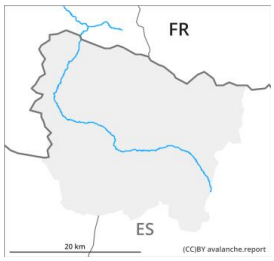
Danger Level 1 — Low

The Avalanche Warning Service currently has only a small amount of information, so that the avalanche danger should be investigated especially thoroughly in the relevant locality.



Avalanche Problems with Core Zones

Wind slab

2400m

Slab avalanche

Snowpack stability: poor

Frequency: few

Avalanche size: small

New snow

2000m

New snow and wind slabs at higher altitudes.

The new snow and wind slabs of the last two days can be released in isolated cases in all aspects and generally at higher altitudes. The avalanche prone locations are to be found in particular adjacent to ridgelines and in gullies and bowls in all aspects and in shady places that are protected from the wind. Very steep sunny slopes intermediate and high altitudes: As a consequence of solar radiation snow slides are possible as the day progresses.

Snowpack

At mid and high altitudes there are 5 to 20 cm of snow, and even more in some localities. The northwesterly wind has transported the new snow. As a consequence of falling temperatures the snowpack will become faceted during the course of the night and therefore lose strength.

Weather

On Friday it will be sunny. The wind will be light.

Development of avalanche danger

1
Friday 27 November 2026

→ **Tendency: Constant avalanche danger**
on Saturday 28 November 2026

The danger of moist snow slides will increase a little during the day. The danger of dry avalanches will decrease gradually.
